Depression and anxiety in sterilised women in Iran

Sterilisation is an effective and convenient means of contraception and has become increasingly popular as a birth control technique throughout the world during the past 40 years. However, some women who choose sterilisation may suffer a neurotic syndrome, which is manifested in the form of depression and loss of libido.1

We undertook a study designed to investigate depression, anxiety and post-operation regret rate in sterilised women referred to health centres in Tabriz, Iran in 2006. The study design was descriptive-analytical. The study participants comprised 300 women in the age range 25–45 years, of whom 150 women were sterilised between 1 and 10 years ago and 150 were a control group of non-sterilised women who used condoms, withdrawal or safe period methods for contraception. The control group was selected by a cluster random sampling method. Fifteen health centres were selected as a cluster from 96 health centres located in Tabriz. Ten women were selected randomly from each health centre using health documents. Women were eligible for inclusion in the study if they were aged between 25 and 45 years at the time of sampling, and if they had no history of psychological disorders and no recent stressful events. There were no differences between the two groups as regards the number of children, income or demographic characteristics.

The women were contacted by telephone at their last known address and were asked to complete a questionnaire. Data collection was done using Zung’s self-rating depression and anxiety scale in addition to questions about post-sterilisation regret. Data were collected from the subjects anonymously and analysed using SPSS (v. 11.5) statistics software. Analysis employed t-test, Chi-square test and descriptive statistics.

The comparison of the means for depression in the two groups was not significantly different (p = 0.96), however the mean of anxiety in the case group was remarkably greater than the control group (p = 0.03). Insufficient post-sterilisation rest was a significant risk factor for depression and anxiety (p = 0.008 and p = 0.02, respectively). Requesting information about reversal after tubal sterilisation was 2.7% and the post-sterilisation regret rate was 6%, which was significantly related to women’s conflict with their husbands about the decision-making process prior to sterilisation (p=0.001).

The study findings as regards psychological disorders of sterilisation suggested that women undergoing sterilisation should ensure that they have a good rest after their operation in order to reduce the extent of psychological disorders. Unlike studies undertaken in other countries,2–4 women’s parity, marriage duration and the timing of sterilisation were unrelated to the women’s regret in our study. The earlier the sterilisation is carried out, the longer the woman’s remaining period of fertile life and the greater the chances of changes in her marital status and/or the loss of a child, both circumstances that may lead to a change in the desired family size and expression of regret. In our study, probably one of the reasons why women’s regret did not appear to be significantly related to young age of sterilisation was the infrequency of divorce or remarriage in our study population. Consistent with our study, Jamieson et al. reported that women who had substantial conflict with their husbands or partners prior to sterilisation were more than three times as likely to regret their decision as those who had less than five times more likely to request a reversal than women who did not report such conflict.5

In our study, pre-sterilisation counselling was reported by 29.3% of subjects. With respect to personality and adaptability differences in facing the changes, pre-sterilisation counselling and post-sterilisation follow-up systems have an important role to play in women’s psychological and psychosexual health promotion.

Difficult insertion of IUS

I would like to present a case of difficult insertion of an intrauterine system (IUS) due to the failure of the device to fully extrude from the applicator despite correct deployment.

The patient, a 34-year-old woman, gravida 3 para 0, wished to have an IUS inserted following a medical termination of pregnancy. The termination had been quite an eventful procedure as the patient had profuse bleeding requiring dilation and curettage and a blood transfusion. When she presented for the IUS fitting the bleeding had completely stopped. The IUS was inserted very easily as per the standard technique but on retrieving the inserter the device was still attached to the inserter (Figure 1). A second attempt with the same device yielded an identical result and it was not until a new device was used that the procedure could be completed successfully. Fearing operator failure, it was of some concern to rule out manufacturing defects. The relative thinness of our patient’s cervical canal following the recent termination might have caused the faulty device to remain trapped in the inserter despite full and correct deployment. Conversely, a similar defective device fitted in a woman with a tighter cervical os might have resulted in the device being released in the uterus but in an abnormally low position after having been dragged by the introducer on its withdrawal. In such a situation the operator would be totally unaware of the device malfunction, and the normally low positioning could lead to device expulsion.

The present case occurred with an IUS but it is not unreasonable to imagine that a similar mechanism could apply to different IUDs such as the TT380 Slimline.6–12 It is thus important to collect for inspection any devices that fail to deploy correctly since this might shed some light on the reasons(s) for expulsion and might perhaps lead to better quality control procedures for the device itself.

Reasons for IUD/IUS removal

Intrauterine devices (IUDs) and the intrauterine system (IUS) are more cost effective than oral contraception.1 Evidence from our clinics suggests that devices were being removed earlier than recommended. We therefore reviewed client contacts during 2005 in two clinics to inquire about the reasons for device removal. Table 1 shows the duration of use at clinic attendance. The lower section of the table shows the duration of use at removal.

Almost half (45%) of the devices were removed because the devices had served their purpose. These were ‘time expired’ (i.e. the device was beyond its recommended duration of use). Seventeen (17.5%) were removed due to bleeding problems, six (11.5%) were extracted and five (12.5%) were removed to facilitate pregnancy.

Failure of intrauterine (IUD) or IUS deployment is likely to be an unreported event since the operator may blame themselves for not having (perhaps inadvertently) correctly deployed the device. However, it is extremely important to inspect all devices that fail in order to rule out manufacturing defects. The relative paucity of our patient’s cervical canal following the recent termination might have caused the faulty device to remain trapped in the inserter despite full and correct deployment. Conversely, a similarly defective device fitted in a woman with a tighter cervical os might have resulted in the device being released in the uterus but in an abnormally low position after having been dragged by the introducer on its withdrawal. In such a situation the operator would be totally unaware of the device malfunction, and the normally low positioning could lead to device expulsion.

Photograph showing intrauterine system device still attached to inserter following unsuccessful deployment.

Table 2 shows the year of removal. Eleven (27.5%) were removed in the first year of use, of which nine were TSafe 380® IUDs. Three of these had extruded and four were removed for bleeding. Eight (20%) were removed in the second year, of which three TSafe 380® IUDs were removed to facilitate pregnancy. More than 50% of the IUS were removed after 5 years. There were no IUS/IUD-related pregnancies.

In the series from the Family Planning and Reproductive Health Research Network, 238 clients had their IUS removed before 5 years for bleeding, medical and other reasons. In our series of IUS there were no removals for bleeding; the most common reason for removal being that the device had reached its recommended duration of use or contraception was no longer required.

Only 42% of all device removals were for problems related to the device itself. Most removals in the first year were of TSafe 380® IUDs. Svin et al. 2 showed the CuT380A device to have a removal rate of 23.3/100 users for bleeding and an expulsion rate of 7.4/100 users at 5 years. Cox et al. 2 speculated that the expulsion rate may be due to the increased copper content or the design of the device. However, could expulsion of the device also be related to the skill or the design of the device. However, could expulsion of the device also be related to the skill of the operator or poor client selection and pre-insertion counselling?

We agree with Cox et al. 2 that counselling before fitting the IUS is important. Likewise, patient careful selection, addressing the concerns of women and their beliefs, 4 and improving communication during consultations 9 helps with compliance in the use of IUDs.

Training GPs to fit IUDs/IUS

Table 2 is delighted to read the article on training general practitioners (GPs) to fit intrauterine devices/intrauterine systems (IUDs/IUSs) by Deborah J Lee in the July 2007 issue of the Journal. 1 Dr Lee has been very proactive in developing alternatives to the traditional format for this specialised training. Having heard about her work I too have been developing a ‘peripatetic’ system for training clinicians, mainly on Dr Lee’s ideas. There are excruciating times ahead; it is possible that practice-based commissioning will lead to a renaissance in the provision of services in the community by primary care. I have some comments:

- I have been training both doctors and nurses – particularly with Implanon® insertion and removal. I have found this technique of reversible contraception (LARC) provision by suitably trained nurses should be available for all women.
- There is a cohort of older GPs who have great skill and many years experience in IUD fitting who do not have any certificates or Letters of Competence (LoC). The National Enhanced Service Contract for primary care accepts their experience under ‘Grandfather’ rules. I have worked with Dr Mohammed Edris to develop a system of revalidation, which involves visiting the practice and observing the clinician fit at least three devices. This visit is also used as an updating and teaching session, reviewing issues such as sterilisation of equipment and current issues. My work has been welcomed by my GP colleagues, who often work in isolated settings. The learning is mutual! I suggest that PCOs spend a day incorporating some sort of a system for all providers with whom they place contracts for IUS/IUD/Implant devices.
- By training practitioners who are in established practice, I know that they will develop their services because they are responding to the needs of their locality. It is different to doctors in training completing another LoC because it will look good on their CV.
- I also do a regular session in a community family planning clinic, and find that the pressure on appointments for LARC makes unhurried training difficult. There is increasing demand for these services when as we know there is little financial investment in the community sexual health services at present.
- My colleagues in training have been supported by drug company financial support. Of course Organon has a motive to ensure that practitioners who fit and remove its implants are suitably trained, as this should reduce litigation. I see this as mutually beneficial. Primary Care Trusts (PCTs) have become very wary of involving drug companies in any form of sponsorship. There is no money specifically available for training in general practice as this is included in the ‘Global Sum’. I am concerned that nurses in particular could lose the opportunity to train, as their GP employers may not see cost benefits. I now suggest that one questionnaire per IUD fitted – this sum is slightly lower than the amount the PCT pays per fit. By training and accrediting, the practice is greatly enhancing its earning potential, only to train the Faculty LoC standard and encourage revalidation.
- My only concern is the issue of indemnity, which was not discussed by Dr Lee. As a visiting clinician undertaking a procedure on a patient registered with another doctor, I assume my liability follows me wherever I go, but my insurance company may need to consider any new risks.
- The National Institute for Health and Clinical Excellence (NICE) guidelines on menorrhagia suggest that women should be offered the IUS. 7 This will not be a contraceptive service. Along with the LARC guidelines, I conclude there will be many women seeking IUS/IUSs/implants.

The vision of a locally accessible service provided by well-trained clinicians will need lots more training in a variety of settings. There is no doubt that the trainers to set up ‘provider’ services that will train and accredit, and which could be profitable.

Training for the LoC IUT

Is it time to alter the criteria for this qualification?

At the moment the training requirement for the Faculty of Family Planning and Reproductive Health Care Letter of Competence in Intrauterine Techniques (LoC IUT) is that the trainee should fit at least two different currently available devices. I have recently had one of my trainees refused her certification because she had only fitted Mirena. I was at a lecture last month given by a representative of a drug company who informed us that when he surveyed their NHS clients, no more than 50% of patients were fitted with Mirena, and that 6% of patients refused her certification because she had only fitted Mirena. I was at a lecture last month given by a representative of a drug company who informed us that when he surveyed their NHS clients, no more than 50% of patients were fitted with Mirena. I was at a lecture last month given by a representative of a drug company who informed us that when he surveyed their NHS clients, no more than 50% of patients were fitted with Mirena, and that 6% of patients refused her certification because she had only fitted Mirena. I was at a lecture last month given by a representative of a drug company who informed us that when he surveyed their NHS clients, no more than 50% of patients were fitted with Mirena, and that 6% of patients refused her certification because she had only fitted Mirena.

I think that the criteria need to be changed. There is now very little demand for copper IUDs in general practice. When patients are given the choice between a device which is not 100% effective and is likely to make their periods heavier, more prolonged and more painful, and one which is much more effective and will make their periods lighter and less painful, it is not surprising that they will mainly choose the Mirena. I was at a lecture last month given by a well-respected family planning instructing doctor. He was saying that copper IUDs were yesterday’s technology and that we should be fitting Mirenas in everyone. ‘I was defending the copper IUD!’ In my own general practice in the past year I have fitted 55 IUDs and only three of them were copper IUDs. Even in my family planning clinic, only 40% of the IUSs are copper IUDs. The Faculty has to recognise the reality of the situation. Most general practitioners (GPs) will only fit Mirenas. If I refuse to provide them with IUDs, I lose the opportunity to train those GPs who wish to train in IUDs.

The Faculty has to recognise the reality of the situation. Most general practitioners (GPs) will only fit Mirenas. If I refuse to provide them with IUDs, I lose the opportunity to train those GPs who wish to train in IUDs.

One of my trainees has recently obtained her LoC and will now have to complete further training. The Faculty has no clear idea how many trainees have obtained their LoC and which are now seeking to obtain additional qualifications. It is possible that they will refuse to provide them with IUDs, I lose the opportunity to train those GPs who wish to train in IUDs.

The Faculty has to recognise the reality of the situation. Most general practitioners (GPs) will only fit Mirenas. If I refuse to provide them with IUDs, I lose the opportunity to train those GPs who wish to train in IUDs.
