Progesterone receptor modulators

The review on ‘Progesterone receptor modulators in gynaecological practice’ in the April 2010 issue of the Journal is a valuable contribution to excellent literature on a currently important subject.

In the section on ‘Contraception’ the authors have dealt at length with mifepristone. Since the latter is not licensed for postcoital contraception, it is not surprising that if the authors dealt with some salient features of the recently introduced second-generation selective progesterone receptor modulator, ulipristal acetate, which is licensed for postcoital contraception for up to 120 hours after unprotected sexual intercourse.

The primary mechanism of action is inhibition of ovulation, but alterations in the endometrium also have anti-implantation effects. Ulipristal acetate appears to be a more potent inhibitor of ovulation than levonorgestrel and hence may be relatively more effective as a method of postcoital contraception.5,7

While the post-implantation use of levonorgestrel has not been associated with any harm to the fetus, as yet the license has not been established for ulipristal acetate.6

We thank Dr Bhathena1 for his interest in our recent review article.2 The purpose of the review was to highlight the many different indications in gynaecological practice, in which progesterone receptor modulators (PRMs) may be applied and to focus on the potential health benefits of PRMs. PRMs have an endometrial antiproliferative effect in the presence of follicular phase estrogen levels, and this constitutes the basis of many of their potential advantages in the management of gynaecological conditions.

Currently, the only licensed indications for PRMs in infertility (preconceptional treatment of pregnancy and ulipristal (UPA) for emergency contraception (EC)) both relate to fertility control. Ulipristal has only recently received a licence based on good evidence of its effectiveness for EC when taken up to 120 hours after intercourse.3,4 This Journal has previously published very informative commentaries and correspondence on the indications and use of ulipristal acetate in emergency contraception.3,5

Like other PRMs, UPA is associated with suppression of ovulation and menstruation via an effect, which may not be explained by its effect as a progesterone antagonist. Registration of UPA followed the publication of the UPA trial and meta-analysis in the Lancet paper.3 The authors of this paper pointed out that regarding the mechanism of action, an effect of UPA on the endometrium could not be ruled out although the effect on ovulation inhibition is potent. With respect to any potential harmful effect on pregnancy, it is reassuring to note that the rate of pregnancy in women treated with levonorgestrel and UPA for EC was not different.

Nurse training in SRH

I have just read the Personal View1 on ‘Nurse training in SRH’ in the January 2010 issue of the Journal and I agree with most of what Shelley Mehigan and Kay Llewellyn discussed in their article.

It would seem sensible that sexual and reproductive healthcare (SRH) training is unified for doctors and nurses. Full membership of the Faculty of Sexual and Reproductive Healthcare (FSRH) should be open to both. Nurse practitioners should be allowed to undertake the same training and sit for the Letters of Competence (LoCs), Diploma of the FSRH (DFSRH) and Membership of the FSRH (MFSRH). SRH, in particular, is ideally suited for such progress. Increasingly, nurse practitioners are providing Level 1 and Level 2 services and doing the bulk of the routine clinical work.

The Mehigan et al. article did not mention that several Colleges already allow other health care practitioners to undertake training and examinations. I am sure that readers are well aware of this; here are some good examples.

1 Faculty of Public Health of the Royal College of Physicians

Other health care professionals, in addition to doctors, may undertake the full training in public health and then be placed on the Voluntary Register of Public Health Examinations. They may not take the MPHP (Membership of Public Health) examination. They may be appointed as Consultants in Public Health and interestingly can act as Medical Directors.

2 Royal College of Pathologists

Training and Membership of the Royal College of Pathologists (MRCPath) is open to scientists, such as virologists and biochemists, and they are not necessarily required to have a medical qualification.

3 Royal College of Surgeons of Edinburgh

The DIMC (Diploma in Immediate Medical Care) (the Royal College of Surgeons of Edinburgh) is open to doctors, nurses and paramedics working in this field.

4 Society of Apothecaries

The DFCASA (Diploma in the Forensic and Clinical Aspects of Sexual Assault) is open to nurses and midwives as well as doctors. This particular diploma is very relevant to SRH practice. The DIMC (Diploma in the Medical Care of Catastrophes) is also open to nurses as well as doctors.

5 University diplomas

Many of the University diplomas are open to a wide range of health care professionals [e.g. the Diploma in Palliative Care of Cardiff University (nurses, doctors) and the Diploma in Medical Law of Northumbria University (nurses, managers, lawyers, doctors)].

6 Medical Royal Colleges and Nurse Training

There should be no great impediment to the Medical Royal Colleges working more closely together with the RCN and universities on unified nurse and doctor training in shared fields.

The Royal Charter of the Royal College of Obstetricians and Gynaecologists states the purpose is: “The encouragement of the study and the advancement of the science and practice of obstetrics and gynaecology”. This is a broad definition and should allow the ROCG and the FSRH to take a progressive view of joint training.

In conclusion, I fully support the Personal View article and would be happy to discuss it further with the authors. I will also be interested to hear about future progress on this issue.

Need for IUD fitters to have expertise in resuscitation

I was pleased to see the Personal View1 article on ‘Nurse training in SRH’ in the January 2010 issue of the Journal.

We have a related issue at the moment and would like to complement comments from other Journal readers. It concerns the Faculty’s guidance on resuscitation for nurses when fitting IUDs.2 It suggests someone competent to give intravenous (IV) drugs must be available. The Royal College of Nursing (RCN) has also made a statement3 supporting this but when contacted the RCN said it supported it because it was Faculty guidance and didn’t seem to understand the consequences or practicalities. It would appear that there is no named person to discuss this matter with there.

We currently have nurse-led community clinics that provide intratubal devices in contraceptive systems (IUDs/IUSs) with no doctor present. Indeed we very few doctors in such clinics.

None of us have ever canulated or given IV drugs (including me for over 20 years). Some people have taken blood from time to time but none of us have any need to do so regularly. We are entirely competent to handle a situation so it would involve weekly IV drug administration, cannulation, which would remove us all from clinic to clinic or theatre to suit or do so. Our resuscitation department is amazed by the guidance.

We surely cannot be the only family planning unit that has predominantly nurse-led clinics, and I cannot believe all IUD fitters have extensive

©FSRH J Fam Plan Reprod Health Care. first published as 10.1783/147118910791749524 on 1 July 2010. Downloaded from J Fam Plan Reprod Health Care: first published as 10.1783/147118910791749524 on 1 July 2010 by guest. Protected by copyright.
experience at IV administration. Perhaps we are unusual in that so many of our nurses do so many procedures.

Do any of you who work in this area feel that nurse training is not keeping pace with changes in society, particularly with the removal of the IUD device where necessary.

I have recently asked over 70 health care professionals who are ‘fit for purpose’. This training must be theoretically and practically robust, be based on sound evidence and the accreditation must not be overly expensive. Our service may still be ‘doctor-led’ in many parts of the UK, but clinics would come to a grinding halt if nurses are restricted in their practice and become ‘handmaidens’ once more. The letter written by Dr Barbara Hollingworth clearly illustrates this point.

We have also had local community nurse-based clinics fitting intrauterine contraceptives in general practice premises suspended because ‘doctor cover’ by the general practitioners [who can administer intravenous (IV) drugs] has been withdrawn. Faculty guidance in Service Standards for Intrauterine Contraception does not clearly state that a health care professional proficient in giving IV drugs is available on site but this is implied by having atropine (0.6 mg/ml) available for IV use.

Clinical Leads should check with their local Ambulance Trusts as many suggest that adrenaline is the only drug that needs to be available within community clinics.

I have recently asked over 70 health care professionals who fit intrauterine contraceptives about their use of atropine and no one has administered it. I have on one occasion in the last 22 years when a woman was very keen to keep an intrauterine device (IUD) in situ as she felt it was her only contraceptive option. On all other occasions when faced with vasovagal attacks any persistent bradycardias have recovered by applying basic life support measures including the removal of the IUD device where necessary.

Perhaps when both these documents are reviewed this issue will be clarified.

Nurse training and the need for IUD fitters to have expertise in resuscitation.

I would like to thank Drs Hollingworth and Mansour for their letters about nurse training and the need for intrauterine device (IUD) fitters to have expertise in resuscitation.1,2 This is a question that I am being increasingly asked by clinicians around the country as they become aware of the implications of recent guidance on this topic. Not only is it unrealistic to expect all the clinicians involved to undertake the extra training and regular practice to comply with the guidance – looking at the British Resuscitation Council guidelines,3 doing what is advised would need advanced life support (ALS)-level training with regular practice of the techniques – it also has implications for how services can be delivered not just by nurses but by doctors too. Many services will feel it is unworkable. Those that have tried, like Dr Hollingworth, to ask the Royal College of Nursing if they had been referred to the Faculty guidance,4 and the Faculty rightly feel that they were following advice from the RCN.

As I understand it, the original guidance from the RCN,5 which was directed at nurses fitting devices rather than assisting other clinicians and was based on discussions with the RCN legal team, advised that a local risk assessment based on how often they felt a problem might arise? Would we insist on the same restrictions for doctors fitting an IUD/implant?

Why might we treat nurses differently?

Issues to consider include:

- Should the nurse fit an IUD very late in the evening?
- If the woman has had a difficult fitting in the past?
- Is there a need to have another registered practitioner (e.g. a doctor) in clinic?
- If a woman had rushed in and had not eaten for hours, and so on?
- Perhaps the way forward would be for one or more groups of nurses to produce guidance for use by all clinicians to follow in such scenarios. This would reflect the multidisciplinary aspect of the work and recognise that this could apply to either doctors or nurses, both groups having highlighted that this is an area where few currently feel able to undertake the actions suggested in the current guidance. If this guidance could be produced following discussion with experts in the field of resuscitation it would then hopefully be realistic, as well as being practical, and would reflect current evidence-based best practice.

Letters to the editor

Safe sex during pregnancy

As a consultant in genitourinary medicine, I wish to comment on Box 1 entitled ‘Is it safe to have sex?’ in Susan Quilliam’s Consumer Correspondent article1 in the April issue of the Journal.

The second point made is that “if either partner has a sexually transmitted infection (STI), they should use protection...”. If one of a couple has an STI then it is generally recommended that for a treatable infection a couple cease completely from having any penetrative sex until treatment of both partners is complete. Condoms do not provide 100% protection against any STI and any untreated infections in pregnancy can carry serious consequences.

I am uncertain why protected anal sex should be “avoided altogether”. If the couple exercises good hygiene practice is there any other concern about using condoms in pregnancy? I could not find anything in the article to explain this advice.

Susan Young, BSc, FRCPI, FRCGP
Consultant in Genitourinary Medicine, Sherwood Forest Hospitals NHS Foundation Trust, King’s Mill Hospital, Sutton in Ashfield, UK.

Reply

First, I wish to thank Dr Young for reading my article1 so carefully and responding to it so thoroughly in her letter.2 Dr Young is, of course, correct that if either partner in a couple has a sexually transmitted infection (STI) they should ideally not have sex at all until after treatment. However, in practice this advice is frequently ignored – particularly during pregnancy when partners want to reinforce their bond and reflect their closeness – so I was being pragmatic in advising protection.

Similarly, Dr Young is correct in saying that in ideal circumstances, anal sex is safe. But in the real-life situations identified I hear about, hygiene practices around anal sex are often far from perfect and so, again pragmatically, during pregnancy in particular I generally advise avoidance.

Finally, the aim of my article, and the substance of the main body of my text, was to promote sex in pregnancy and ask professionals to encourage it. I didn’t aim to give detailed information about risks – such information is covered fully in many other sources. Hence the guidance provided in the summary boxes gives headlines only rather than explaining in full the medical background.
