**Sexual discussion as consultation**

At this point, of course, we come up against hard reality. Because I know that the vision I’ve outlined above – to have all health professionals actively considering happy sexual functioning as part of their patient’s good health – will be tricky to achieve.

On a practical level, I’m very aware that it is difficult even for sexual specialists like ourselves to initiate conversations about a client’s love life; how much more difficult, then, for the general medical professional to dive in? Most don’t see, read and speak ‘sex talk’ as a regular part of their job. They don’t have experience of normalising such conversations for their patients. They may feel utterly de-resourced to advise practically (more challengingly still, to support emotionally.) They may have no idea how, or where, to refer on.

Helping patients who want to be sexually active to be so is a vital part of any medical care.

And even if the practicalities of enrolling non-specialists were solved, there may still be an insurmountable belief barrier to overcome. Not every practitioner will realise how important it is for them to include sexual functioning in their practice. They may feel that sex is ‘an optional extra’ in a patient’s life. (And yes, for many patients it is; many patients neither want nor need a regular love life and I would be the first to argue that that is their choice, and not their failure.)

**Sexual activity as a lifestyle marker**

But I would also be the first to argue that for many patients having a regular, loving sex life is hugely important. For most, losing desire means they lose self-esteem; becoming non-functional means they become deskillled, often depressed. They may feel unable to turn to their partner even for simple affection, for fear that they then won’t be able to perform; in the end they feel not only unloved and unlovable but also unloving. And this in the context of already suffering the physical pain and emotional debilitation that illness – particularly chronic illness – brings. Can there be any doubt that helping patients who want to be sexually active to be so is a vital part of any medical care?

In short, I would argue that if we want to mobilise non-sexual specialists as I’m suggesting, the most crucial step is to get our entire profession to acknowledge the vital role that sexuality plays in health. We need to move beyond regarding sex as something only specialist sexual health professionals pay attention to, and then only when it goes wrong. We need to reach a stage where all practitioners see positive sexuality as an integral part of diagnosis, treatment and general health care.

This compact clinical guide gives an up-to-date overview of the common gynaecological complaint of abnormal uterine bleeding. It is immediately apparent that the author, Malcolm Munro, has real enthusiasm for his speciality and a genuine desire to improve patient care. The book proceeds to describe common gynaecological procedures used in the treatment of abnormal uterine bleeding. This section is fantastically supplemented with an inclusive DVD of real-time procedures with helpful commentaries. As for the negative aspects, the book does take some serious reading as there is abundant, albeit interesting, prose. A clinician seeking a quick reference guide would probably be better off looking elsewhere.

**BOOK REVIEW**

This compact clinical guide gives an up-to-date overview of the common gynaecological complaint of abnormal uterine bleeding. It is immediately apparent that the author, Malcolm Munro, has real enthusiasm for his speciality and a genuine desire to improve patient care. The book is divided into five sections: background, anatomy and physiology, classification and pathogenesis, clinical management, and procedures. The introductory historical context provides an entertaining and informative insight into how far we have progressed in the understanding of the pathogenesis and treatment of abnormal bleeding. Clear illustrations and diagrams guide the reader through the complexities of the anatomy and physiology of menstruation. Munro addresses the inconsistencies in nomenclature in relation to abnormal bleeding and provides a useful summary of the internationally agreed new PALM-COEIN classification system. The clinical management section provides a practical, evidence-based approach with useful flow charts to aid physician decision-making. The book proceeds to describe common gynaecological procedures used in the treatment of abnormal uterine bleeding. This section is fantastically supplemented with an inclusive DVD of real-time procedures with helpful commentaries. As for the negative aspects, the book does take some serious reading as there is abundant, albeit interesting, prose. A clinician seeking a quick reference guide would probably be better off looking elsewhere.
