I, Sex Robot: the health implications of the sex robot industry

Chantal Cox-George,1 Susan Bewley2

INTRODUCTION
The sex technology industry is already estimated to be worth US$30 billion.1 While sex toys are well-established, sex robots (‘sexbots’), anthropomorphic devices created for sexual gratification, are no longer science fiction. Four companies sell adult sexbots priced between US$5000 and US$15 000. They must be distinguished from ‘paedobots’—childlike robotic models at present only produced by one company.2 The market appears to be men, and so far only ‘female’ adult sexbots have been created, although one company reports aiming to sell ‘male’ devices later in 2018.3 Sex robots are realistic mannequins with variable ages, appearances and textures, and customisable oral, vaginal and anal openings.

The medical profession needs to be prepared for inevitable questions about the impact of sex robots on health. Apart from free-market profits, the majority of arguments in their favour use ‘harm limitation’ somewhat defensively to convince others that this is one way to protect the vulnerable. Opponents reject the hypothesis that they reduce sexual crimes, and instead raise concerns about the potential for harm by further promoting the pervasive idea that living women too are sex objects that should be constantly available—‘misogynistic objectification’—and intensifying existing physical and sexual violence against women and children.

What characterises all discussions of this issue is the paucity of an evidence base. This might falsely reassure clinicians not to concern themselves with changing their current clinical practice. However, an absence of evidence does not excuse the medical profession from discussing and debating the issues, as there will inevitably be consequences for physical, mental and social well-being.

METHODOLOGY
We aim to provide a succinct summary of the arguments for and against the sex robot industry and to assess the potential health implications that may affect both patients and clinicians. To find information about the health consequences of sex robot use a narrative literature review via PubMed and Google was conducted, using the terms ‘robot’, ‘sex’, ‘sex toys’, ‘doll’, ‘child sex abuse’, ‘sex therapy’, ‘paedophile’ with follow-up of embedded references, and informal discussions with expert informants from various specialties. In order to explore the themes identified, we considered sexbots within the contexts of pornography, sex dolls and virtual reality.

We found no reports of primary data relating to health aspects of the use of sex robots.

THEMES IDENTIFIED
We identified four key themes relevant to healthcare providers:

► Safer sex
► Therapeutic potential
► Potential to treat paedophiles and sex offenders
► Changing societal norms.

Do sex robots promote safer sex?
Some people envision a future with no sex trafficking, sex tourism or sex trade. One hypothetical future red-light district has been described where the spread of sexually transmitted infections is prevented by providing robotic prostitutes made of bacteria-resistant fibre, flushed for human fluids after use.4 This well-intentioned scenario is optimistic, and sexbots can already be bought, or leased for parties. There may be legal liability ramifications should the engineering of sexbots fail, leading to injury or infection, and with unclear responsibility for condoms and cleaning protocols.5
Do sex robots have therapeutic value?
Psychosexual therapists should examine the future impact of sex robots on empathy and human relationships. It is at least plausible that sex robots will be helpful for patients who would benefit from sexual practice without pressure, although this might move some further away from human intimacy. Sexual activity with robots has been described as a masturbatory practice, so someone with sexual dysfunction, which may already lead to isolation, “might become even more isolated by the illusion of having a substitute satisfaction”. Psychosexual therapists might use sexbots to assist couples with mismatched libido or to help treat erectile dysfunction, but potential adverse consequences, such as rejection of the non-interacting partner or threats to the integrity of the relationship, are underplayed. Sexbots might provide ‘companionship’ for the lonely, mentally and physically disabled, the elderly, or those who find intercourse traumatic, though this justification requires a change in meaning of ‘companion’ from a living, interacting person. It also seems patronising to argue for a ‘lesser’ sexual experience when most people with disabilities can form mutually satisfying relationships. Artificial intelligence means sexbots will move, eye-track, ‘speak’ and simulate sexual functions as they “adapt to their user’s needs and even moods”. However, it remains unproven that intimacy ‘needs’ will be satisfied: there could be worsened distress. While a human may genuinely desire a sexbot, reciprocation can only be artificially mimicked.

Do sex robots have potential to treat paedophiles and sex offenders?
Even before sexbots, there was little consensus on the impact of pornography, although there are claims of an association with reduced incidences of rape and prostitution, confounded by causality, transparency and recognition that there are conflicts of interest. Countervailing risks have been expressed including commodifying human beings, normalising sexual deviancy, becoming ‘addictive’, acting as a practice ground for violence, and promoting the control of vulnerable individuals. While many sexbot users may distinguish between fact and fantasy, some buyers may not, leading to concern about potentially exacerbating the risk of sexual assault and rape of actual children and adults.

Virtual reality has been shown to evoke realistic (and potentially gratifying) responses in sexually deviant and non-deviant men in controlled research settings. One company (with a decade’s experience producing life-like child sex dolls) claims that they help individuals “redirect dark desires”, thus protecting potential victims. The company’s chief executive officer, a man with self-confessed paedophilic impulses, believes that aberrant sexual desires cannot be remedied but instead should be expressed legally and ethically, otherwise life would not be “worth living”. This might be taken literally or seen as a manipulative suicide threat.

In the USA, virtual child pornography is considered legally distinct from imagery involving real children. In the UK, it would not be illegal to own a child sexbot, although a man has been jailed for “importing an obscene article”, a child sex doll. Forensic physicians working in Sexual Assault Referral Centres have been involved in police investigations of customs offences, providing age assessment of child sex dolls (size, age-related features, Tanner staging, hair, clothing) (L O’Connor, ME Vooijs, S Lewis, C White, K Shardlow, BP Butler, personal communications, 2017).

Given present major weaknesses in the evidence base, and the lack of evidence of effective treatments of sexual offenders against children, we would strongly caution against the use of paedobots as putative ‘treatment’ unless as part of robust, scientifically and ethically acceptable research trials.

Will there be changes in societal norms?
Sexbots are generally female and ‘air-brushed’, raising the question of public interest in avoiding gender discrimination and inequality due to the promotion of distorted views of attractiveness that reduce female body confidence. There are worries about blurred boundaries to consent and permission for enacted violence when sexbot ‘personalities’ can be selected that simulate non-consensual sex - that is, rape. The Foundation for Responsible Robotics states that the sex between human and robot is intrinsically different to sex between humans because “machinery … cannot grant consent or be raped” But can the user’s motivation be entirely discounted? An established UK judgement determined that consent does not protect against charges of unlawful and malicious wounding and assault occasioning actual bodily harm.

If therapeutic benefit were demonstrated, would doctors ‘prescribe’ sexbots based on ‘harm reduction’,
and how would onward use be controlled? It would not be surprising if some doctors had conscientious objections based on feeling professionally or morally compromised. Even if sexbots ‘worked’ and contributed to health, the products’ high cost would presumably limit accessibility.

CONCLUSIONS

Evidence-based healthcare is at the core of medical professionalism and practice. The current dearth of information on health aspects of sexbots may relate to rapid commercial innovation, low sales, few direct consultations, failure to recognise and report health and social consequences for patients, or inadequate investment in research.

However, absent evidence of efficacy of both therapeutic value and sexual satisfaction will hardly dampen market forces. Potential profits and rising demand will incentivise companies to produce cheaper sexbots. Technological advances will drive competition to create the most affordable but desirable model. Research has explored ‘robotiquette’ for the management of human-robot interactions. We call for more research in this sphere. Future health studies might include medical observations, case reports, and measurement of visual and neural responses of users, alongside evidence of the impact of robots, and sexbots in particular, in the education, criminal justice and social science sectors.

The UK General Medical Council and medical defence organisations have not issued any guidance, but doctors might be advised to avoid using sexbots themselves, given police interest, prosecutions, and the potential negative impact on public trust.

The overwhelmingly predominant market for sexbots will be unrelated to healthcare. Thus the ‘health’ arguments made for their benefits, as with so many advertised products, are rather specious. Currently, the ‘precautionary principle’ should reject the clinical use of sexbots until their postulated benefits, namely ‘harm limitation’ and ‘therapy’, have been tested empirically.

Acknowledgements The authors wish to thank the many colleagues who offered insights but who withheld their names out of discretion.

Contributors CCG is an Academic Foundation Year 2 Doctor at St George’s Hospital in London with interests in sexual and reproductive health. She researched and drafted the article. SB is Professor of Women’s Health at King’s College London. She advised and edited the article. Both authors approved the final version.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient consent Not required.

Provenance and peer review Not commissioned; externally peer reviewed.

Data sharing statement No additional data available.

The current marketing health claims made for ‘sexbots’—lifelike robots specifically created for sexual gratification—are misleading as there is no good evidence to back them up, suggest experts in an editorial published online in BMJ Sexual & Reproductive Health.

The sex technology industry is already worth US$ 30 billion, and sexbots are set to boost that figure further. Although currently targeted to men, one company reportedly plans to sell male versions for women later this year.

The specification of sexbots can be tailor-made according to personal preference, and their use has often been defended on the health related grounds of ‘harm reduction,’ and their supposed ability to curb the incidence of sex crimes and sexual violence against women and children, explain Dr Chantal Cox-George, St George's University Hospitals NHS Foundation Trust and Professor Susan Bewley, Women's Health Academic Centre, King's College London.

To try and explore the reported health related pros and cons of sexbots further, and answer some of the questions clinicians will inevitably be faced with, the authors trawled a comprehensive research database, carried out internet searches, and discussed the issues with various different experts.

They didn’t find a single study on the health implications of sexbots. But their research threw up four key themes: safer sex; therapeutic potential; treatment for paedophiles; changing societal norms.

It is thought that sexbots might have the potential to eliminate sex trafficking, tourism, and prostitution and encourage safer sex with the provision of sexbots made of washable bacteria resistant fibres.

But this is somewhat fanciful, suggest the authors, adding that it’s not clear who would bear responsibility for condoms and cleaning protocols.

“It is speculative whether the development of a sexbot marketplace will lead to lesser risk of violence and infections, or drive further exploitation of human sex workers,” they write.

The idea that sexbots could be used to treat relationship difficulties, erectile dysfunction, and enforced celibacy as a result of ill health, aging, disability, or loss of a partner is plausible, they suggest.

But equally, these devices might make existing problems worse and are hardly likely to satisfy intimacy needs and reciprocate desire, they point out.
And it has been suggested that sexbots might be used to ‘treat’ paedophilia or prevent sexual violence by providing an acceptable outlet for these urges. But they might instead help to normalise sexual deviancy or act as a practice ground for violence, including rape, say the authors.

Then there’s the issue of the ‘airbrushed’ appearance of sexbots, which are generally hairless, so helping to distort perceptions of female attractiveness, they point out.

The lack of evidence is hardly likely to dampen market forces, say the authors, who suggest that sexbots are likely to become more affordable and more technologically advanced, so fuelling demand.

“The overwhelming predominant market for sexbots will be unrelated to healthcare. Thus the ‘health’ arguments made for their benefits, as with so many advertised products, are rather specious,” they write.

“Currently the precautionary principle should reject the clinical use of sexbots until their postulated benefits, namely ‘harm limitation’ and ‘therapy’ have been tested empirically,” they conclude.
